NAME
>   perlmroapi - Perl method resolution plugin interface

DESCRIPTION
>   As of Perl 5.10.1 there is a new interface for plugging and using method resolution orders other than the default (linear depth first search). The C3 method resolution order added in 5.10.0 has been re-implemented as a plugin, without changing its Perl-space interface.
>
>   Each plugin should register itself by providing the following structure

```
struct mro_alg {
AV *(*resolve)(pTHX_ HV *stash, U32 level);
const char *name;
U16 length;
U16 kflags;
U32 hash;
};
```

>   and calling `Perl_mro_register`:

```
Perl_mro_register(aTHX_ &my_mro_alg);
```

>   resolve
>>   Pointer to the linearisation function, described below.
>
>   name
>>   Name of the MRO, either in ISO-8859-1 or UTF-8.
>
>   length
>>   Length of the name.
>
>   kflags
>>   If the name is given in UTF-8, set this to `HVhek_UTF8`. The value is passed direct as the parameter *kflags* to `hv_common()`.
>
>   hash
>>   A precomputed hash value for the MRO's name, or 0.

Callbacks
>   The `resolve` function is called to generate a linearised ISA for the given stash, using this MRO. It is called with a pointer to the stash, and a *level* of 0. The core always sets *level* to 0 when it calls your function - the parameter is provided to allow your implementation to track depth if it needs to recurse.
>
>   The function should return a reference to an array containing the parent classes in order. The names of the classes should be the result of calling `HvENAME()` on the stash. In those cases where `HvENAME()` returns null, `HvNAME()` should be used instead.
>
>   The caller is responsible for incrementing the reference count of the array returned if it wants to keep the structure. Hence, if you have created a temporary value that you keep no pointer to, `sv_2mortal()` to ensure that it is disposed of correctly. If you have cached your return value, then return a pointer to it without changing the reference count.

Caching
>   Computing MROs can be expensive. The implementation provides a cache, in which you can store a single `SV *`, or anything that can be cast to `SV *`, such as `AV *`. To read your private value, use the macro `MRO_GET_PRIVATE_DATA()`, passing it the `mro_meta` structure from the stash, and a pointer to your `mro_alg` structure:

```
meta = HvMROMETA(stash);
private_sv = MRO_GET_PRIVATE_DATA(meta, &my_mro_alg);
```

>   To set your private value, call `Perl_mro_set_private_data()`:

```
Perl_mro_set_private_data(aTHX_ meta, &c3_alg, private_sv);
```

The private data cache will take ownership of a reference to private_sv, much the same way that `hv_store()` takes ownership of a reference to the value that you pass it.

Examples

For examples of MRO implementations, see `S_mro_get_linear_isa_c3()` and the `BOOT:` section of *ext/mro/mro.xs*, and `S_mro_get_linear_isa_dfs()` in *mro_core.c*

AUTHORS

The implementation of the C3 MRO and switchable MROs within the perl core was written by Brandon L Black. Nicholas Clark created the pluggable interface, refactored Brandon's implementation to work with it, and wrote this document.
