

NAME

chroot - change root directory

SYNOPSIS

```
#include <unistd.h>
```

```
int chroot(const char *path);
```

Feature Test Macro Requirements for glibc (see [feature_test_macros\(7\)](#)):

chroot():

Since glibc 2.2.2:

```
_BSD_SOURCE ||  
(_XOPEN_SOURCE >= 500 ||  
_XOPEN_SOURCE && _XOPEN_SOURCE_EXTENDED) &&  
!(_POSIX_C_SOURCE >= 200112L || _XOPEN_SOURCE >= 600)
```

Before glibc 2.2.2: none

DESCRIPTION

chroot() changes the root directory of the calling process to that specified in *path*. This directory will be used for pathnames beginning with /. The root directory is inherited by all children of the calling process.

Only a privileged process (Linux: one with the **CAP_SYS_CHROOT** capability) may call **chroot()**.

This call changes an ingredient in the pathname resolution process and does nothing else.

This call does not change the current working directory, so that after the call '.' can be outside the tree rooted at '/. In particular, the superuser can escape from a "chroot jail" by doing:

```
mkdir foo; chroot foo; cd ..
```

This call does not close open file descriptors, and such file descriptors may allow access to files outside the chroot tree.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and *errno* is set appropriately.

ERRORS

Depending on the filesystem, other errors can be returned. The more general errors are listed below:

EACCES

Search permission is denied on a component of the path prefix. (See also [path_resolution\(7\)](#).)

EFAULT

path points outside your accessible address space.

EIO An I/O error occurred.

ELOOP

Too many symbolic links were encountered in resolving *path*.

ENAMETOOLONG

path is too long.

ENOENT

The file does not exist.

ENOMEM

Insufficient kernel memory was available.

ENOTDIR

A component of *path* is not a directory.

EPERM

The caller has insufficient privilege.

CONFORMING TO

SVr4, 4.4BSD, SUSv2 (marked LEGACY). This function is not part of POSIX.1-2001.

NOTES

A child process created via [fork\(2\)](#) inherits its parent's root directory. The root directory is left unchanged by [execve\(2\)](#).

FreeBSD has a stronger **jail**(`jail()`) system call.
