

NAME

chroot - change root directory

SYNOPSIS

```
#include <unistd.h>
```

```
int chroot(const char *path);
```

Feature Test Macro Requirements for glibc (see [feature_test_macros\(7\)](#)):

chroot():

Since glibc 2.2.2:

```
    _BSD_SOURCE ||
    (_XOPEN_SOURCE >= 500 ||
     _XOPEN_SOURCE && _XOPEN_SOURCE_EXTENDED) &&
    !(_POSIX_C_SOURCE >= 200112L || _XOPEN_SOURCE >= 600)
```

Before glibc 2.2.2: none

DESCRIPTION

chroot() changes the root directory of the calling process to that specified in *path*. This directory will be used for pathnames beginning with */*. The root directory is inherited by all children of the calling process.

Only a privileged process (Linux: one with the **CAP_SYS_CHROOT** capability) may call **chroot()**.

This call changes an ingredient in the pathname resolution process and does nothing else.

This call does not change the current working directory, so that after the call *.* can be outside the tree rooted at */*. In particular, the superuser can escape from a chroot jail by doing:

```
mkdir foo; chroot foo; cd ..
```

This call does not close open file descriptors, and such file descriptors may allow access to files outside the chroot tree.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and *errno* is set appropriately.

ERRORS

Depending on the filesystem, other errors can be returned. The more general errors are listed below:

EACCES

Search permission is denied on a component of the path prefix. (See also [path_resolution\(7\)](#).)

EFAULT

path points outside your accessible address space.

EIO An I/O error occurred.

ELOOP

Too many symbolic links were encountered in resolving *path*.

ENAMETOOLONG

path is too long.

ENOENT

The file does not exist.

ENOMEM

Insufficient kernel memory was available.

ENOTDIR

A component of *path* is not a directory.

EPERM

The caller has insufficient privilege.

CONFORMING TO

SVr4, 4.4BSD, SUSv2 (marked LEGACY). This function is not part of POSIX.1-2001.

NOTES

A child process created via [fork\(2\)](#) inherits its parent's root directory. The root directory is left unchanged by [execve\(2\)](#).

FreeBSD has a stronger [jail\(\)](#) system call.
