NAME

getsockname - get socket name

SYNOPSIS

#include <sys/socket.h>

int getsockname(int sockfd, struct sockaddr *addr, socklen_t *addrlen);

DESCRIPTION

getsockname() returns the current address to which the socket *sockfd* is bound, in the buffer pointed to by *addr*. The *addrlen* argumen t should be initialized to indicate the amount of space (in bytes) pointed to by *addr*. On return it contains the actual size of the socket address.

The returned address is truncated if the buffer provided is too small; in this case, address will return a value greater than was supplied to the call.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and errno is set appropriately.

ERRORS

EBADF

The argument *sockfd* is not a valid descriptor.

EFAULT

The addr argument points to memory not in a valid part of the process address space.

EINVAL

addrlen is invalid (e.g., is negative).

ENOBUFS

Insufficient resources were available in the system to perform the operation.

ENOTSOCK

The argument sockfd is a file, not a socket.

CONFORMING TO

SVr4, 4.4BSD (the **getsockname**() function call appeared in 4.2BSD), POSIX.1-2001.

NOTES

The third argument of **getsockname**() is in reality an int * (and this is what 4.x BSD and libc4 and libc5 have). Some POSIX confusion resulted in the present $socklen_t$, also used by glibc. See also accept(2).

SEE ALSO

bind(2), socket(2), getifaddrs(3), ip(7), socket(7), unix(7)
