

NAME

mknod, mknodat - create a special or ordinary file

SYNOPSIS

```
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>
```

```
int mknod(const char *pathname, mode_t mode, dev_t dev);
```

```
#include <fcntl.h> /* Definition of AT_* constants */
#include <sys/stat.h>
```

```
int mknodat(int dirfd, const char *pathname, mode_t mode, dev_t dev);
```

Feature Test Macro Requirements for glibc (see [feature_test_macros\(7\)](#)):

```
mknod():
```

```
    _BSD_SOURCE || _SVID_SOURCE || _XOPEN_SOURCE >= 500 ||
    _XOPEN_SOURCE && _XOPEN_SOURCE_EXTENDED
```

DESCRIPTION

The system call **mknod()** creates a filesystem node (file, device special file, or named pipe) named *pathname*, with attributes specified by *mode* and *dev*.

The *mode* argument specifies both the permissions to use and the type of node to be created. It should be a combination (using bitwise OR) of one of the file types listed below and the permissions for the new node.

The permissions are modified by the process's *umask* in the usual way: the permissions of the created node are (*mode* & ~*umask*).

The file type must be one of **S_IFREG**, **S_IFCHR**, **S_IFBLK**, **S_IFIFO**, or **S_IFSOCK** to specify a regular file (which will be created empty), character special file, block special file, FIFO (named pipe), or UNIX domain socket, respectively. (Zero file type is equivalent to type **S_IFREG**.)

If the file type is **S_IFCHR** or **S_IFBLK**, then *dev* specifies the major and minor numbers of the newly created device special file ([makedev\(3\)](#) may be useful to build the value for *dev*); otherwise it is ignored.

If *pathname* already exists, or is a symbolic link, this call fails with an **EEXIST** error.

The newly created node will be owned by the effective user ID of the process. If the directory containing the node has the set-group-ID bit set, or if the filesystem is mounted with BSD group semantics, the new node will inherit the group ownership from its parent directory; otherwise it will be owned by the effective group ID of the process.

mknodat()

The **mknodat()** system call operates in exactly the same way as [mknod\(2\)](#), except for the differences described here.

If the *pathname* given in *pathname* is relative, then it is interpreted relative to the directory referred to by the file descriptor *dirfd* (rather than relative to the current working directory of the calling process, as is done by [mknod\(2\)](#) for a relative *pathname*).

If *pathname* is relative and *dirfd* is the special value **AT_FDCWD**, then *pathname* is interpreted relative to the current working directory of the calling process (like [mknod\(2\)](#)).

If *pathname* is absolute, then *dirfd* is ignored.

See [openat\(2\)](#) for an explanation of the need for **mknodat()**.

RETURN VALUE

mknod() and **mknodat()** return zero on success, or -1 if an error occurred (in which case, *errno* is set appropriately).

ERRORS

EACCES

The parent directory does not allow write permission to the process, or one of the directories in the path prefix of *pathname* did not allow search permission. (See also [path_resolution\(7\)](#).)

EDQUOT

The user's quota of disk blocks or inodes on the filesystem has been exhausted.

EEXIST

pathname already exists. This includes the case where *pathname* is a symbolic link, dangling or not.

EFAULT

pathname points outside your accessible address space.

EINVAL

mode requested creation of something other than a regular file, device special file, FIFO or socket.

ELOOP

Too many symbolic links were encountered in resolving *pathname*.

ENAMETOOLONG

pathname was too long.

ENOENT

A directory component in *pathname* does not exist or is a dangling symbolic link.

ENOMEM

Insufficient kernel memory was available.

ENOSPC

The device containing *pathname* has no room for the new node.

ENOTDIR

A component used as a directory in *pathname* is not, in fact, a directory.

EPERM

mode requested creation of something other than a regular file, FIFO (named pipe), or UNIX domain socket, and the caller is not privileged (Linux: does not have the **CAP_MKNOD** capability); also returned if the filesystem containing *pathname* does not support the type of node requested.

EROFS

pathname refers to a file on a read-only filesystem.

The following additional errors can occur for **mknodat()**:

EBADF

dirfd is not a valid file descriptor.

ENOTDIR

pathname is relative and *dirfd* is a file descriptor referring to a file other than a directory.

VERSIONS

mknodat() was added to Linux in kernel 2.6.16; library support was added to glibc in version 2.4.

CONFORMING TO

mknod(): SVr4, 4.4BSD, POSIX.1-2001 (but see below), POSIX.1-2008.

mknodat(): POSIX.1-2008.

NOTES

POSIX.1-2001 says: The only portable use of **mknod()** is to create a FIFO-special file. If *mode* is not **S_IFIFO** or *dev* is not 0, the behavior of **mknod()** is unspecified. However, nowadays one should never use **mknod()** for this purpose; one should use [mkfifo\(3\)](#), a function especially defined for this purpose.

Under Linux, **mknod()** cannot be used to create directories. One should make directories with [mkdir\(2\)](#).

There are many infelicities in the protocol underlying NFS. Some of these affect **mknod()** and [mknodat\(2\)](#).
