

**NAME**

addseverity - introduce new severity classes

**SYNOPSIS**

```
#include <fmtmsg.h>
```

```
int addseverity(int severity, const char *s);
```

Feature Test Macro Requirements for glibc (see [feature\\_test\\_macros\(7\)](#)):

```
addseverity(): _SVID_SOURCE
```

**DESCRIPTION**

This function allows the introduction of new severity classes which can be addressed by the *severity* argument of the [fmtmsg\(3\)](#) function. By default that latter function only knows how to print messages for severity 0-4 (with strings (none), HALT, ERROR, WARNING, INFO). This call attaches the given string *s* to the given value *severity*. If *s* is NULL, the severity class with the numeric value *severity* is removed. It is not possible to overwrite or remove one of the default severity classes. The severity value must be nonnegative.

**RETURN VALUE**

Upon success, the value **MM\_OK** is returned. Upon error, the return value is **MM\_NOTOK**. Possible errors include: out of memory, attempt to remove a nonexistent or default severity class.

**VERSIONS**

`addseverity()` is provided in glibc since version 2.1.

**CONFORMING TO**

This function is not specified in the X/Open Portability Guide although the [fmtmsg\(3\)](#) function is. It is available on System V systems.

**NOTES**

New severity classes can also be added by setting the environment variable **SEV\_LEVEL**.
