NAME

basename, dirname - parse pathname components

SYNOPSIS

```
#include <libgen.h>
char *dirname(char *path);
char *basename(char *path);
```

DESCRIPTION

Warning: there are two different functions **basename**() - see below.

The functions **dirname**() and **basename**() break a null-terminated pathname string into directory and filename components. In the usual case, **dirname**() returns the string up to, but not including, the final /, and **basename**() returns the component following the final /. Trailing / characters are not counted as part of the pathname.

If path does not contain a slash, **dirname()** returns the string . while **basename()** returns a copy of path. If p ath is the string /, then both **dirname()** and **basename()** return the string /. If path is a null pointer or points to an empty string, then both **dirname()** and **basename()** return the string ..

Concatenating the string returned by **dirname**(), a /, and the string returned by **basename**() yields a complete pathname.

Both **dirname**() and **basename**() may modify the contents of *path*, so it may be desirable to pass a copy when calling one of these functions.

These functions may return pointers to statically allocated memory which may be overwritten by subsequent calls. Alternatively, they may return a pointer to some part of *path*, so that the string referred to by *path* should not be modified or freed until the pointer returned by the function is no longer required.

The following list of examples (taken from SUSv2) shows the strings returned by **dirname**() and **basename**() for different paths:

path	$\operatorname{\mathbf{dirname}}$	basename
/usr/lib	/usr	lib
/usr/	/	usr
usr	•	usr
/	/	/
	•	

RETURN VALUE

Both dirname() and basename() return pointers to null-terminated strings. (Do not pass these pointers to free(3).)

ATTRIBUTES

Multithreading (see pthreads(7))

The **basename**() and **dirname**() functions are thread-safe.

CONFORMING TO

POSIX.1-2001.

NOTES

There are two different versions of **basename**() - the POSIX version described above, and the GNU version, which one gets after

```
#define _GNU_SOURCE /* See feature_test_macros(7)
*/
#include <string.h>
```

The GNU version never modifies its argument, and returns the empty string when *path* has a trailing slash, and in particular also when it is /. There is no GNU version of **dirname**().

With glibc, one gets the POSIX version of basename() when < libgen.h> is included, and the GNU version otherwise.

BUGS

In the glibc implementation of the POSIX versions of these functions they modify their argument, and segfault when called with a static string like /usr/. Before glibc 2.2.1, the glibc version of **dirname()** did not correctly handle pathnames with trailing / characters, and generated a segfault if given a NULL argument.

EXAMPLE

```
char *dirc, *basec, *bname, *dname;
char *path = /etc/passwd;
dirc = strdup(path);
basec = strdup(path);
dname = dirname(dirc);
bname = basename(basec);
printf(dirname=%s, basename=%sn, dname, bname);
```

SEE ALSO

basename(1), dirname(1)
