#### **NAME**

carg, cargf, cargl - calculate the complex argument

## **SYNOPSIS**

```
#include <complex.h>
double carg(double complex z);
float cargf(float complex z);
long double cargl(long double complex z);
```

Link with -lm.

## **DESCRIPTION**

A complex number can be described by two real coordinates. One may use rectangular coordinates and gets

```
z = x + I * y
where x = creal(z) and y = cimag(z).
Or one may use polar coordinates and gets
z = r * cexp(I * a)
```

where r = cabs(z) is the radius, the modulus, the absolute value of z, and a = carg(z) is the phase angle, the argument of z.

One has:

```
tan(carg(z)) = cimag(z) / creal(z)
```

## RETURN VALUE

The return value is the range of [-pi,pi].

#### **VERSIONS**

These functions first appeared in glibc in version 2.1.

## CONFORMING TO

C99.
