

NAME

`catan`, `catanf`, `cataln` - complex arc tangents

SYNOPSIS

```
#include <complex.h>

double complex catan(double complex z);
float complex catanf(float complex z);
long double complex cataln(long double complex z);
```

Link with `-lm`.

DESCRIPTION

The `catan()` function calculates the complex arc tangent of z . If $y = \operatorname{atan}(z)$, then $z = \operatorname{ctan}(y)$. The real part of y is chosen in the interval $[-\pi/2, \pi/2]$.

One has:

$$\operatorname{atan}(z) = (\operatorname{clog}(1 + i * z) - \operatorname{clog}(1 - i * z)) / (2 * i)$$

VERSIONS

These functions first appeared in glibc in version 2.1.

CONFORMING TO

C99.

EXAMPLE

```
/* Link with "-lm" */

#include <complex.h>
#include <stdlib.h>
#include <unistd.h>
#include <stdio.h>

int
main(int argc, char *argv[])
{
    double complex z, c, f;
    double complex i = I;

    if (argc != 3) {
        fprintf(stderr, "Usage: %s <real> <imag>\n", argv[0]);
        exit(EXIT_FAILURE);
    }

    z = atof(argv[1]) + atof(argv[2]) * I;
    c = catan(z);
    printf("catan() = %6.3f %6.3f*i\n", creal(c), cimag(c));

    f = (clog(1 + i * z) - clog(1 - i * z)) / (2 * i);
    printf("formula = %6.3f %6.3f*i\n", creal(f2), cimag(f2));

    exit(EXIT_SUCCESS);
}
```
