NAME

gethostbyname, gethostbyname2, gethostbyname3, gethostbyname3

SYNOPSIS

```
#include <netdb.h>
    extern int h errno;
    struct hostent *gethostbyname(const char *name);
    #include <sys/socket.h> /* for AF INET */
    struct hostent *gethostbyaddr(const void *addr,
    socklen t len, int type);
    void sethostent(int stayopen);
    void endhostent(void);
    void herror(const char *s);
    const char *hstrerror(int err);
    /* System V/POSIX extension */
    struct hostent *gethostent(void);
    /* GNU extensions */
    struct hostent *gethostbyname2(const char *name, int af);
    int gethostent r(
    struct hostent *ret, char *buf, size t buflen,
    struct hostent **result, int *h errnop);
    int gethostbyaddr r(const void *addr, socklen t len, int type,
    struct hostent *ret, char *buf, size t buflen,
    struct hostent **result, int *h errnop);
    int gethostbyname r(const char *name,
    struct hostent *ret, char *buf, size t buflen,
    struct hostent **result, int *h errnop);
    int gethostbyname2 r(const char *name, int af,
    struct hostent *ret, char *buf, size t buflen,
    struct hostent **result, int *h errnop);
Feature Test Macro Requirements for glibc (see feature test macros(7)):
    gethostbyname2(), gethostent r(), gethostbyaddr r(), gethostbyname r(), gethostby-
    name2 r():
        BSD SOURCE | SVID SOURCE
    herror(), hstrerror():
        Since glibc 2.8:
            BSD SOURCE || SVID SOURCE
        Before glibc 2.8:
            none
    h errno:
        Since glibc 2.12:
            BSD SOURCE || SVID SOURCE || ( POSIX C SOURCE < 200809L &&
            XOPEN SOURCE < 700)
```

2014-03-11

```
Before glibc 2.12: none
```

DESCRIPTION

The **gethostbyname***(), **gethostbyaddr***(), **herror**(), and **hstrerror**() functions are obsolete. Applications should use getaddrinfo(3), getnameinfo(3), and gai strerror(3) instead.

The **gethostbyname**() function returns a structure of type *hostent* for the given host *name*. Here name is either a hostname, or an IPv4 address in standard dot notation (as for inet_addr(3)), or an IPv6 address in colon (and possibly dot) notation. (See RFC 1884 for the description of IPv6 addresses.) If name is an IPv4 or IPv6 address, no lookup is performed and **gethostbyname**() simply copies name into the h_name field and its struct in_naddr equivalent into the $h_naddr_list[0]$ field of the returned hostent structure. If name doesn't end in a dot and the environment variable **HOSTALIASES** is set, the alias file pointed to by **HOSTALIASES** will first be searched for name (see hostname(7) for the file format). The current domain and its parents are searched unless name ends in a dot.

The **gethostbyaddr**() function returns a structure of type *hostent* for the given host address *addr* of length *len* and address type *type*. Valid address types are **AF_INET** and **AF_INET6**. The host address argument is a pointer to a struct of a type depending on the address type, for example a *struct in addr* *(probably obtained via a call to inet addr(3)) for address type **AF INET**.

The **sethostent**() function specifies, if *stayopen* is true (1), that a connected TCP socket should be used for the name server queries and that the connection should remain open during successive queries. Otherwise, name server queries will use UDP datagrams.

The **endhostent**() function ends the use of a TCP connection for name server queries.

The (obsolete) **herror**() function prints the error message associated with the current value of h_errno on stderr.

The (obsolete) **hstrerror**() function takes an error number (typically h_errno) and returns the corresponding message string.

The domain name queries carried out by **gethostbyname**() and **gethostbyaddr**() use a combination of any or all of the name server **named(8)**, a broken out line from /etc/hosts, and the Network Information Service (NIS or YP), depending upon the contents of the order line in /etc/host.conf. The default action is to querynamed(8), followed by /etc/hosts.

The *hostent* structure is defined in $\langle netdb.h \rangle$ as follows:

```
struct hostent {
    char *h_name; /* official name of host */
    char **h_aliases; /* alias list */
    int h_addrtype; /* host address type */
    int h_length; /* length of address */
    char **h_addr_list; /* list of addresses */
}
#define h addr h addr list[0] /* for backward compatibility */
```

The members of the *hostent* structure are:

 h_name

The official name of the host.

 $h_aliases$

An array of alternative names for the host, terminated by a null pointer.

 $h_addrtype$

The type of address; always AF INET or AF INET6 at present.

2014-03-11 2

h length

The length of the address in bytes.

h addr list

An array of pointers to network addresses for the host (in network byte order), terminated by a null pointer.

h addr The first address in h addr list for backward compatibility.

RETURN VALUE

The **gethostbyname**() and **gethostbyaddr**() functions return the *hostent* structure or a null pointer if an error occurs. On error, the h_errno variable holds an error number. When non-NULL, the return value may point at static data, see the notes below.

ERRORS

The variable h errno can have the following values:

HOST NOT FOUND

The specified host is unknown.

NO ADDRESS or NO DATA

The requested name is valid but does not have an IP address.

NO RECOVERY

A nonrecoverable name server error occurred.

TRY AGAIN

A temporary error occurred on an authoritative name server. Try again later.

FILES

```
/etc/host.conf resolver configuration file /etc/hosts host database file /etc/nsswitch.conf name service switch configuration
```

CONFORMING TO

POSIX.1-2001 specifies **gethostbyname**(), **gethostbyaddr**(), **sethostent**(), **endhostent**(), **gethostent**(), and h_errno ; **gethostbyname**(), **gethostbyaddr**(), and h_errno are marked obsolescent in that standard. POSIX.1-2008 removes the specifications of **gethostbyname**(), **gethostbyaddr**(), and h_errno , recommending the use of **getaddrinfo**(3) and **getnameinfo**(3) instead.

NOTES

The functions **gethostbyname**() and **gethostbyaddr**() may return pointers to static data, which may be overwritten by later calls. Copying the *struct hostent* does not suffice, since it contains pointers; a deep copy is required.

In the original BSD implementation the len argument of **gethostbyname**() was an int. The SUSv2 standard is buggy and declares the len argument of **gethostbyaddr**() to be of type $size_t$. (That is wrong, because it has to be int, and $size_t$ is not. POSIX.1-2001 makes it $socklen_t$, which is OK.) See also accept(2).

The BSD prototype for **gethostbyaddr**() uses const char * for the first argument.

System V/POSIX extension

POSIX requires the **gethostent**() call, that should return the next entry in the host data base. When using DNS/BIND this does not make much sense, but it may be reasonable if the host data base is a file that can be read line by line. On many systems a routine of this name reads from the file /etc/hosts. It may be available only when the library was built without DNS support. The glibc version will ignore ipv6 entries. This function is not reentrant, and glibc adds a

2014-03-11 3

reentrant version **gethostent** $\mathbf{r}()$.

GNU extensions

Glibc2 also has a **gethostbyname2**() that works like **gethostbyname**(), but permits to specify the address family to which the address must belong.

Glibc2 also has reentrant versions $\operatorname{\mathbf{gethostent_r}}()$, $\operatorname{\mathbf{gethostbyaddr_r}}()$, $\operatorname{\mathbf{gethostbyname_r}}()$ and $\operatorname{\mathbf{gethostbyname2_r}}()$. The caller supplies a hostent structure r et which will be filled in on success, and a temporary work buffer buf of size buflen. After the call, r esult will point to the result on success. In case of an error or if no entry is found result will be NULL. The functions return 0 on success and a nonzero error number on failure. In addition to the errors returned by the nonreentrant versions of these functions, if buf is too small, the functions will return $\operatorname{\mathbf{ERANGE}}$, and the call should be retried with a larger buffer. The global variable h_errnop is not modified, but the address of a variable in which to store error numbers is passed in h_errnop .

BUGS

 $\mathbf{gethostbyname}()$ does not recognize components of a dotted IPv4 address string that are expressed in hexadecimal.
