NAME

DSA generate parameters ex, DSA generate parameters - generate DSA parameters

SYNOPSIS

```
#include <openssl/dsa.h>
int DSA_generate_parameters_ex(DSA *dsa, int bits,
  const unsigned char *seed,int seed_len,
  int *counter_ret, unsigned long *h_ret, BN_GENCB *cb);

Deprecated:

DSA *DSA_generate_parameters(int bits, unsigned char *seed,
  int seed_len, int *counter_ret, unsigned long *h_ret,
  void (*callback)(int, int, void *), void *cb_arg);
```

DESCRIPTION

DSA_generate_parameters_ex() generates primes p and q and a generator g for use in the DSA and stores the result in dsa.

bits is the length of the prime to be generated; the DSS allows a maximum of 1024 bits.

If **seed** is **NULL** or **seed_len** < 20, the primes will be generated at random. Otherwise, the seed is used to generate them. If the given seed does not yield a prime q, a new random seed is chosen and placed at **seed**.

DSA_generate_parameters_ex() places the iteration count in *counter_ret and a counter used for finding a generator in *h_ret, unless these are NULL.

A callback function may be used to provide feedback about the progress of the key generation. If **cb** is not **NULL**, it will be called as shown below. For information on the BN_GENCB structure and the BN GENCB call function discussed below, refer to BN generate prime(3).

- When a candidate for q is generated, $BN_GENCB_call(cb, 0, m++)$ is called (m is 0 for the first candidate).
- When a candidate for q has passed a test by trial division, BN_GENCB_call(cb, 1, -1) is called. While a candidate for q is tested by Miller-Rabin primality tests, BN_GENCB_call(cb, 1, i) is called in the outer loop (once for each witness that confirms that the candidate may be prime); i is the loop counter (starting at 0).
- When a prime q has been found, BN_GENCB_call(cb, 2, 0)and BN_GENCB_call(cb, 3, 0)are called.
- Before a candidate for p (other than the first) is generated and tested, BN_GENCB_call(cb, 0, counter) is called.
- When a candidate for p has passed the test by trial division, BN_GENCB_call(cb, 1, -1) is called. While it is tested by the Miller-Rabin primality test, BN_GENCB_call(cb, 1, i) is called in the outer loop (once for each witness that confirms that the candidate may be prime). i is the loop counter (starting at 0).
- When p has been found, BN_GENCB_call(cb, 2, 1) is called.
- When the generator has been found, BN_GENCB_call(cb, 3, 1)is called.

 $DSA_generate_parameters()$ (deprecated) works in much the same way as for DSA_generate_parameters_ex, except that no **dsa** parameter is passed and instead a newly allocated **DSA** structure is returned. Additionally "old style" callbacks are used instead of the newer BN_GENCB based approach. Refer to $BN_generate_prime(3)$ for further information.

RETURN VALUE

DSA_generate_parameters_ex() returns a 1 on success, or 0 otherwise.

DSA_generate_parameters() returns a pointer to the DSA structure, or NULL if the parameter

generation fails.

The error codes can be obtained by ERR get error(3).

BUGS

Seed lengths > 20 are not supported.

HISTORY

 $DSA_generate_parameters()$ appeared in SSLeay 0.8. The **cb_arg** argument was added in SSLeay 0.9.0. In versions up to OpenSSL 0.9.4, **callback(1, ...)**w as called in the inner loop of the Miller-Rabin test whenever it reached the squaring step (the parameters to **callback** did not reveal how many witnesses had been tested); since OpenSSL 0.9.5, **callback(1, ...)** is called as in $BN_is_prime(3)$, i.e. once for each witness.
