

NAME

tty_ioctl - ioctls for terminals and serial lines

SYNOPSIS

```
#include <termios.h>
```

```
int ioctl(int fd, int cmd, ...);
```

DESCRIPTION

The `ioctl(2)` call for terminals and serial ports accepts many possible command arguments. Most require a third argument, of varying type, here called *argp* or *arg*.

Use of *ioctl* makes for nonportable programs. Use the POSIX interface described in [termios\(3\)](#) whenever possible.

Get and set terminal attributes

TCGETS **struct termios** *argp

Equivalent to `tcgetattr(fd, argp)`.

Get the current serial port settings.

TCSETS **const struct termios** *argp

Equivalent to `tcsetattr(fd, TCSANOW, argp)`.

Set the current serial port settings.

TCSETSW **const struct termios** *argp

Equivalent to `tcsetattr(fd, TCSADRAIN, argp)`.

Allow the output buffer to drain, and set the current serial port settings.

TCSETSF **const struct termios** *argp

Equivalent to `tcsetattr(fd, TCSAFLUSH, argp)`.

Allow the output buffer to drain, discard pending input, and set the current serial port settings.

The following four ioctls are just like **TCGETS**, **TCSETS**, **TCSETSW**, **TCSETSF**, except that they take a *struct termio* * instead of a *struct termios* *.

TCGETA **struct termio** *argp

TCSETA **const struct termio** *argp

TCSETAW **const struct termio** *argp

TCSETAF **const struct termio** *argp

Locking the termios structure

The *termios* structure of a terminal can be locked. The lock is itself a *termios* structure, with nonzero bits or fields indicating a locked value.

TIOCGLOCKTRMIO **struct termios** *argp

Gets the locking status of the *termios* structure of the terminal.

TIOCSLOCKTRMIO **const struct termios** *argp

Sets the locking status of the *termios* structure of the terminal. Only a process with the **CAP_SYS_ADMIN** capability can do this.

Get and set window size

Window sizes are kept in the kernel, but not used by the kernel (except in the case of virtual consoles, where the kernel will update the window size when the size of the virtual console changes, for example, by loading a new font).

The following constants and structure are defined in `<sys/ioctl.h>`.

TIOCGWINSZ **struct winsize** *argp

Get window size.

TIOCSWINSZ const struct winsize *argp

Set window size.

The struct used by these ioctls is defined as

```
struct winsize {
    unsigned short ws_row;
    unsigned short ws_col;
    unsigned short ws_xpixel; /* unused */
    unsigned short ws_ypixel; /* unused */
};
```

When the window size changes, a **SIGWINCH** signal is sent to the foreground process group.

Sending a break**TCSBRK int arg**

Equivalent to *tcsendbreak(fd, arg)*.

If the terminal is using asynchronous serial data transmission, and *arg* is zero, then send a break (a stream of zero bits) for between 0.25 and 0.5 seconds. If the terminal is not using asynchronous serial data transmission, then either a break is sent, or the function returns without doing anything. When *arg* is nonzero, nobody knows what will happen.

(SVr4, UnixWare, Solaris, Linux treat *tcsendbreak(fd, arg)* with nonzero *arg* like *tcdrain(fd)*. SunOS treats *arg* as a multiplier, and sends a stream of bits *arg* times as long as done for zero *arg*. DG/UX and AIX treat *arg* (when nonzero) as a time interval measured in milliseconds. HP-UX ignores *arg*.)

TCSBRKP int arg

So-called "POSIX version" of **TCSBRK**. It treats nonzero *arg* as a time interval measured in deciseconds, and does nothing when the driver does not support breaks.

TIOCSBRK void

Turn break on, that is, start sending zero bits.

TIOCCBRK void

Turn break off, that is, stop sending zero bits.

Software flow control**TCXONC int arg**

Equivalent to *tcflow(fd, arg)*.

See [tcflow\(3\)](#) for the argument values **TCOOFF**, **TCOON**, **TCIOFF**, **TCION**.

Buffer count and flushing**FIONREAD int *argp**

Get the number of bytes in the input buffer.

TIOCINQ int *argp

Same as **FIONREAD**.

TIOCOUTQ int *argp

Get the number of bytes in the output buffer.

TCFLSH int arg

Equivalent to *tcflush(fd, arg)*.

See [tcflush\(3\)](#) for the argument values **TCIFLUSH**, **TCOFLUSH**, **TCIOFLUSH**.

Faking input**TIOCSTI const char *argp**

Insert the given byte in the input queue.

Redirecting console output

TIOCCONS void

Redirect output that would have gone to `/dev/console` or `/dev/tty0` to the given terminal. If that was a pseudoterminal master, send it to the slave. In Linux before version 2.6.10, anybody can do this as long as the output was not redirected yet; since version 2.6.10, only a process with the **CAP_SYS_ADMIN** capability may do this. If output was redirected already **EBUSY** is returned, but redirection can be stopped by using this ioctl with `fd` pointing at `/dev/console` or `/dev/tty0`.

Controlling terminal**TIOCSCTTY int *arg***

Make the given terminal the controlling terminal of the calling process. The calling process must be a session leader and not have a controlling terminal already. For this case, *arg* should be specified as zero.

If this terminal is already the controlling terminal of a different session group, then the ioctl fails with **EPERM**, unless the caller has the **CAP_SYS_ADMIN** capability and *arg* equals 1, in which case the terminal is stolen, and all processes that had it as controlling terminal lose it.

TIOCNOTTY void

If the given terminal was the controlling terminal of the calling process, give up this controlling terminal. If the process was session leader, then send **SIGHUP** and **SIGCONT** to the foreground process group and all processes in the current session lose their controlling terminal.

Process group and session ID**TIOCGPGRP pid_t **argp***

When successful, equivalent to `*argp = tcgetpgrp(fd)`.

Get the process group ID of the foreground process group on this terminal.

TIOCSGRP const pid_t **argp*

Equivalent to `tcsetpgrp(fd, *argp)`.

Set the foreground process group ID of this terminal.

TIOCGSID pid_t **argp*

Get the session ID of the given terminal. This will fail with **ENOTTY** in case the terminal is not a master pseudoterminal and not our controlling terminal. Strange.

Exclusive mode**TIOCEXCL void**

Put the terminal into exclusive mode. No further `open(2)` operations on the terminal are permitted. (They will fail with **EBUSY**, except for a process with the **CAP_SYS_ADMIN** capability.)

TIOCGEXCL int **argp*

If the terminal is currently in exclusive mode, place a nonzero value in the location pointed to by *argp*; otherwise, place zero in **argp* (since Linux 3.8).

TIOCNXCL void

Disable exclusive mode.

Line discipline**TIOCGETD int **argp***

Get the line discipline of the terminal.

TIOCSETD const int **argp*

Set the line discipline of the terminal.

Pseudoterminal ioctls**TIOCPKT const int **argp***

Enable (when **argp* is nonzero) or disable packet mode. Can be applied to the master side of a pseudoterminal only (and will return **ENOTTY** otherwise). In packet mode, each subsequent `read(2)` will return a packet that either contains a single nonzero control byte, or has a single byte containing zero (' ') followed by data written on the slave side of the pseudoterminal. If the first byte is not **TIOCPKT_DATA** (0), it is an OR of one or more of the following bits:

TIOCPKT_FLUSHREAD The read queue for the terminal is flushed.
TIOCPKT_FLUSHWRITE The write queue for the terminal is flushed.
TIOCPKT_STOP Output to the terminal is stopped.
TIOCPKT_START Output to the terminal is restarted.
TIOCPKT_DOSTOP The start and stop characters are `^S/^Q`.
TIOCPKT_NOSTOP The start and stop characters are not `^S/^Q`.

While this mode is in use, the presence of control status information to be read from the master side may be detected by a [select\(2\)](#) for exceptional conditions.

This mode is used by [rlogin\(1\)](#) and [rlogind\(8\)](#) to implement a remote-echoed, locally `^S/^Q` flow-controlled remote login.

TIOGCPKT const int *argp

Return the current packet mode setting in the integer pointed to by *argp* (since Linux 3.8).

TIOCSPTLCK int *argp

Set (if **argp* is nonzero) or remove (if **argp* is zero) the pseudoterminal slave device. (See also [unlockpt\(3\)](#).)

TIOCGPTLCK int *argp

Place the current lock state of the pseudoterminal slave device in the location pointed to by *argp* (since Linux 3.8).

The BSD ioctls **TIOCSTOP**, **TIOCSTART**, **TIOCUCNTL**, **TIOCREMOTE** have not been implemented under Linux.

Modem control

TIOCMGET int *argp

Get the status of modem bits.

TIOCMSET const int *argp

Set the status of modem bits.

TIOCMBIC const int *argp

Clear the indicated modem bits.

TIOCMBIS const int *argp

Set the indicated modem bits.

The following bits are used by the above ioctls:

TIOCM_LE DSR (data set ready/line enable)

TIOCM_DTR DTR (data terminal ready)

TIOCM_RTS RTS (request to send)

TIOCM_ST Secondary TXD (transmit)

TIOCM_SR Secondary RXD (receive)

TIOCM_CTS CTS (clear to send)

TIOCM_CAR DCD (data carrier detect)

TIOCM_CD see **TIOCM_CAR**

TIOCM_RNG RNG (ring)

TIOCM_RI see **TIOCM_RNG**

TIOCM_DSR DSR (data set ready)

TIOCMWAIT int arg

Wait for any of the 4 modem bits (DCD, RI, DSR, CTS) to change. The bits of interest are specified as a bit mask in *arg*, by ORing together any of the bit values, **TIOCM_RNG**, **TIOCM_DSR**, **TIOCM_CD**, and **TIOCM_CTS**. The caller should use **TIOCGICOUNT** to see which bit has changed.

TIOCGICOUNT struct serial_icounter_struct *argp

Get counts of input serial line interrupts (DCD, RI, DSR, CTS). The counts are written to the *serial_icounter_struct* structure pointed to by *argp*.

Note: both 1->0 and 0->1 transitions are counted, except for RI, where only 0->1 transitions are counted.

Marking a line as local

TIOCGSOFTCAR *int *argp*

("Get software carrier flag") Get the status of the CLOCAL flag in the *c_cflag* field of the *termios* structure.

TIOCSSOFTCAR *const int *argp*

("Set software carrier flag") Set the CLOCAL flag in the *termios* structure when **argp* is nonzero, and clear it otherwise.

If the **CLOCAL** flag for a line is off, the hardware carrier detect (DCD) signal is significant, and an [open\(2\)](#) of the corresponding terminal will block until DCD is asserted, unless the **O_NONBLOCK** flag is given. If **CLOCAL** is set, the line behaves as if DCD is always asserted. The software carrier flag is usually turned on for local devices, and is off for lines with modems.

Linux-specific

For the **TIOCLINUX** ioctl, see [console_ioctl\(4\)](#).

Kernel debugging

#include <linux/tty.h>

TIOCTTYGSTRUCT *struct tty_struct *argp*

Get the *tty_struct* corresponding to *fd*. This command was removed in Linux 2.5.67.

RETURN VALUE

The [ioctl\(2\)](#) system call returns 0 on success. On error, it returns -1 and sets *errno* appropriately.

ERRORS

EINVAL

Invalid command parameter.

ENOIOCTLCMD

Unknown command.

ENOTTY

Inappropriate *fd*.

EPERM

Insufficient permission.

EXAMPLE

Check the condition of DTR on the serial port.

```
#include <termios.h>
#include <fcntl.h>
#include <sys/ioctl.h>

int
main(void)
{
    int fd, serial;

    fd = open("/dev/ttyS0", O_RDONLY);
    ioctl(fd, TIOCMGET, &serial);
    if (serial & TIOCM_DTR)
        puts("TIOCM_DTR is set");
    else
        puts("TIOCM_DTR is not set");
    close(fd);
}
```
